1. Preface

Automation testing is an emerging field that draws maximum benefits with minimum effort. Then benefit of automation testing is its ability to increase the efficiency of resources, increase test coverage, and increase the quality and reliability of the software.

While there are several frameworks that provide support for automated software testing, this document introduces one particularly effective type: the Open Source Test Automation Framework.

In the Open Source Test Automation Framework, the discrete functional business events that make up an application are described using keywords. This approach fosters code reusability, optimum utilization of the tool, and greater productivity.
2. Framework Overview

2.1. Introduction to Framework

Automation testing requires a well defined approach, based on a comprehensive framework, in order to reap maximum benefits.

A **framework** is a hierarchical directory that encapsulates shared resources, such as a dynamic shared library, image files, localized strings, header files, and reference documentation in a single package.

There are various frameworks available for automation, such as:
- Test Script Modularity Framework
- Test Library Architecture Framework
- Data-driven Automation Framework
- Hybrid Automation Framework
- Keyword-driven Automation Framework

Keyword-based test design and test automation is formed on the idea that the discrete functional business events that make up any application can be described using short text description (keywords). By designing keywords that describe those discrete functional business events, testers begin to build a common library of keywords that can be used to create test scripts.

The Open Source Test Automation Framework is a keyword-driven automation framework that works with HP QuickTest Professional (QTP). This framework allows testers to develop test cases using Microsoft Excel and a list of keywords. When the test is executed, the framework processes the Excel workbook and calls functions associated with the keywords entered in the Excel spreadsheet. These keyword functions in turn perform specific actions against the application under test (AUT). The framework interprets the keyword and executes a set of statements in the program.

With this framework in place, applications can be automated without starting from scratch. Testers simply use the application independent keywords and create extra application-specific keywords.

2.2. Framework Features

In addition to standard features such as performing operations and verifications on the objects, the framework includes other sophisticated features, such as:

1. **Use of variables:** Variables can be defined and used across the generated test script. This can be used to capture runtime values, which can be reused as input elsewhere during test execution.
2. **Conditional checking**: Conditional constructs such as ‘if’ can be implemented using keywords to handle different flows based on various conditions.

3. **Data-driven testing**: This framework supports data-driven testing by importing data from an external data sheet.

4. **Reports**: Customized reporter messages can also be used to perform effective analysis on execution reports. These reports can be customized to display the pass or fail condition of any functionality, even during the verification of any checkpoints.

5. **Calling functions and reusable actions**: Common functions or actions can be triggered through keywords. This framework supports a functional decomposition approach. This increases the reusability of functions, which in turn reduces the unnecessary repetition of steps.

6. **Keyboard inputs**: This plug-in is included to perform keyboard actions on the specified test object.

7. **Date/time functions**: The date/time function plug-in is included to perform different operations on date/time.

8. **Exception handling**: Runtime errors can be effectively handled and reported using this framework.

9. **Handling object (Web or windows)**: If QTP is unable to identify the specific object type class to which the recorded object belongs, QTP identifies it as a Web or Windows Object. Some operations can be performed on the Web or as a Windows Object using keywords.

### 2.3. Framework Benefits

**Reusability:**

The Open Source Test Automation Framework is an application-independent framework that deals with all possible actions and verifications that can be performed on an object. Therefore, the code for the same object can be used across different applications.

Duplication of work is minimized at every level. For instance, a user might have to perform a certain action on an object of a similar class (e.g., clicking a button) repeatedly. This can be in the same test case or in a different application altogether. In both cases, the same code can be reused.

**Optimum utilization of the tool:**

The framework has the advantage of using keywords as the input for triggering an action. This well built framework uses the features of the tool effectively. For instance, QTP uses a shared object repository where all the objects required can be added and reused across the scripts for an application under test.
**Less effort:**

The effort involved in coding and reviewing is minimal when compared to other frameworks since a good percentage of coding is done within the framework. The tester simply has to enter the keywords, reducing the time required for coding. Recording is also not required as the global repository is used. The amount of rework required for migrating from one application to the other on the same platform is reduced since the code remains the same.

**Increased quality:**

The scripts will be of uniform quality since they make use of the same code.

**Greater productivity:**

The Open Source Test Automation Framework provides both qualitative and quantitative benefits for automation and is highly productive compared to any other framework. This framework also addresses the ongoing maintenance of the test scripts in a cost-effective manner.

**Maintenance:**

Simple modifications to the application can be easily handled in the code. The changes will be done only in the external file containing the code and the scripts need not be changed. Hence it is easy-to-maintain the scripts and provide cost-effective solution for the test automation.

**No scripting skills required by the end user:**

No coding skills required to automate and to review the scripts. The scripts are user friendly with good readability. Scripts can be interpreted easily by a person who does not have complete knowledge of the tool.

**Return on investment is high:**

Although the initial effort for building framework is high, in the long run, the return on investment will be high because of the reusability and optimum utilization of the tool.
3. Framework Architecture

3.1. Framework Architecture

Architecture forms the foundation of any software application. It should be robust enough to handle the desired functions efficiently and effectively. In this approach, the goal is to develop an application independent reusable keyword framework that can be used directly across any application without spending any extra time on it.

In order to make all the components of the system work in sync, it is important to define the components, its functionalities, as well as the binding relationship between them.

An Automation Framework Architecture comprises of the following components:

- **Framework**
  
  The framework consists of the following sub-components, namely:
  
  - Function Library
  - Common Functions

- **Abstract Layer**
  
  The abstract layer consists of the following sub-components, namely:
  
  - The Object Repository
  - Driver Script
  - Keywords

- **External Data**
  
  External data consists of the following sub-components, namely:
  
  - Data Sheets
  - Global Variables
3.1.1. **Driver Script**

The driver script (DS) drives the script execution. It is the few lines of script in the QTP main window that will invoke the process of synchronizing the keywords with the framework and the object repository. This script calls the functions from the function library, which reads the keywords, objects, and parameters and performs appropriate actions as per the functions in the function library. By incorporating the DS with the framework in a separate function, the effort required to develop the DS is reduced. A call to the function will act as the DS.

3.1.2. **Function Library**

The function Library (FL) forms the backbone of the Automation Framework. All the coding logic is in the form of a user-defined VB script. All these functions are stored in the FL. It is the place where most of the scripts reside and the place where customization can be done in the script for the project. The FL is the only component in the framework that has to be changed in case the application is migrating from one platform to the other. This addition and deletion of functions makes the framework flexible enough to use it for any other application.
3.1.3. Common Function

The common functions (CF) are the functions that are reusable across all platforms. These functions are application independent, and do not depend on the technology that has been used to develop the application. Separating the CFs from the function library ensures maximum utilization of reusable scripts, and in turn reduces the maintenance effort of scripts. Some of the common functions include conditional functions, loop functions, etc.

Syntax for function

fun <fun name>(arg1,arg2)<br>
<Statements><br>
end

For example if u want to call mul(3,6)
Call mul(3,6)
function mul(a,b)<br>
mul=a*b<br>
end

3.1.4. Object Repository

QTP learns the interface of an application by learning the application's objects and their corresponding property values and objects descriptions. The Object Repository is the place where QTP recognizes and stores information such as properties, values, etc.

With this object repository, the tool identifies the application and executes the business flows as per the functions in the test script. If any one or more of the object's property values in the application differs from the property values stored in the object repository, the tool will not identify the object and the script will fail. Therefore it is necessary to change the property value in the object repository if it differs from the property value in the application.

Test objects can be stored in two types of object repositories:

- Shared object repository – objects stored in a file that can be shared and accessed by multiple tests (in read-only mode)
- Local object repository – objects stored in a file that is related with one specific action, so that only that action can access the stored objects

A combination of both local and shared object repositories can also be used. The best practice here is to keep a shared repository that can be used across all test cases.
3.1.5. Keywords

Keywords trigger specific functions in the framework to perform a specific operation on the desired object in the application. These keywords are fed in the data table of QTP or as an input Excel sheet, which will be fed in by the driver script. The data table records contain the keywords that describe the desired actions. This also provides additional data needed as input to the application, the benchmark information to verify the state of components, and the application in general.

Ideally, the keyword (vocabulary) should be written in such a way that the keywords are recognizable and suitable for manual testing. Achieving this crossover capability allows us to create one test case for both automated and manual test cases. It is this feature which makes the Keyword-drive Framework powerful.

3.1.6. External Test Data

External test data is given as inputs to the test scripts to perform the same operations on the application using different set of data. This spreadsheet holds multiple combinations of inputs to be fed to test the application. External test data can also be given as an input sheet during checking operations. The best practice here is to keep the data sheet in a common place, preferably in the test management tool.

3.1.7. Global Variables

Global variables to be used across all the test cases should be defined and kept in a common place and should be provided as an input to the framework. After defining a variable to refer to a test object, you can use the variable instead of the entire object hierarchy in other statements. Using variables in this way makes the script easier to read and to maintain. These global variables can also be used to store runtime values and used again in another script.

3.1.8. Reporting

After execution of the test script, it is necessary to get the results of the execution. Apart from the test execution report generated by the QTP tool, testers can customize reports in an external spreadsheet format. This provides report details for which test scripts have failed or passed while running a test suite. The reports detail exceptional cases handled, defects found, and error logged. These functions are customized in the driver script. This helps in performing effective analysis on the execution report.
4. **Flow Diagram of the Open Source Test Automation Framework**

![Flow Diagram](image)

**Note:**

The values within [ ] are optional, usage depends on the scenario

**Figure 2: Flow Diagram**

At the start of the test execution, the driver script is invoked. The function library contains all the code for the actions identified. The driver script traverses through keywords, and each keyword triggers the function library to perform the desired action on the application.
5. Conclusion

Analysis is an important and time-consuming phase of automation testing. However, in the long run, the time spent will be useful during the regression phase. In order to keep up with the pace of product development and delivery it is essential to implement effective, reusable test automation. The Open Source Test Automation Framework provides a way to drive productivity and foster code reuse — ultimately enhancing the quality of resulting software.
